The goal is not to understand every single thing about this organic chemistry mechanism in great detail right now. Our goal right now is just to appreciate how nucleophiles and electrophiles are used in organic chemistry mechanisms and start to get a feeling for how these curved arrows show the movement or flow of electrons.

In this video, we were able to get a mechanism. We can talk in the future about how likely it is to happen, how quickly it might happen. We were able to start with hydrogen bromide and 1-pentene, or pent-1-ene, and get to this thing, just by pushing around electrons and just thinking about what is likely to happen based on what's electronegative and what might be able to gain or lose an electron.

Organic reactions are chemical reactions involving organic compounds. The basic organic chemistry reaction types are addition reactions, elimination reactions, substitution reactions, pericyclic reactions, rearrangement reactions, photochemical reactions and redox reactions. In organic synthesis, organic reactions are used in the construction of new organic molecules.

The use of these symbols in bond-breaking and bond-making reactions is illustrated below. If a covalent single bond is broken so that one electron of the shared pair remains with each fragment, as in the first example, this bond-breaking is called homolysis. If the bond breaks with both electrons of the shared pair remaining with one fragment, as in the second and third examples, this is called ...
